## (57) Abstract

A computer system has a large number of media input sources selectively coupled to a single presentation device. A device database tracks characteristics and connections of the input sources. Multiple, possibly conflicting, channels are assigned to a set of mutually distinct logical channel designations in a channel-map database. Program events occurring on the channels reside in a guide database.

## **CHANNEL MAP MANAGER FOR MULTIPLE INPUT DEVICES**

5

### **Related Applications**

This application is related to the co-assigned and co-filed applications, "Method and system for associating web sites to television programs," "System for time-shifting events in a multi-channel convergence system," "Individualized parameter control for multiple media sources in a data processing system,"  
10 "System for combining electronic program guide data," "System for scheduled caching of in-band data services," "Integration of Internet sources into an electronic program database list," "Previous, favorite, and frequent channel management system," "System, apparatus, and method for tuning a television to a selected channel," "System for resolving channel selection in a multi-channel  
15 system," and "A system for managing favorite channels," all of which are hereby incorporated by reference.

### **Background of the Invention**

The present invention relates to electronic data processing, and more  
20 particularly concerns the identification, selection, and presentation of media signals from multiple channels of multiple media sources in a multimedia system.

Personal computers are evolving in several different directions. One of those directions leads toward a larger system including multimedia inputs from  
25 many different sources, presented to a user—or a group of users simultaneously—through a set of system output devices which have a configuration similar to that of an entertainment center or a home theater. This type of personal computer converges the capabilities of previously separate systems into a single system having greater capabilities than any of the separate  
30 systems, and at the same time reduces cost by eliminating the duplication of components providing the same function in the separate systems. An example of such a "converged system" is the publicly available Destination® PC/TV system from Gateway 2000. This product permits a user to enjoy the capabilities of

both a personal computer system and a high-quality television system at a lower total cost than that of two separate systems.

One of the advantages of a convergence system is the availability of enough computing power to integrate many media input devices, such as direct-broadcast satellite receivers, compact disc and digital video disc players, video cassette recorders, and cameras, and to control their functions from a central point. Moreover, the programmability of a computer permits a system to be built up and configured to the individual tastes of each user, and to allow the media devices to interact with each other as the user wishes. Another potential capability involves employing on-line programming guides to set up and schedule events, such as recording a particular satellite show on a cassette recorder, then playing it back at a specified time.

In order to realize the advantages of convergence systems, it must be very easy for a relatively untrained user to add new features and devices, to prevent devices from interfering with each other, and to present consistent interfaces for all features and devices.

One of the problems in meeting these goals is that individual media sources such as satellite, cable, and off-the-air television each have multiple channels, and their channels are numbered or otherwise designated without regard for the designations of channels in the other services. Each service has its own, incompatible "channel map." Thus, for example, merely specifying channel '156' may be ambiguous between a local cable provider and a satellite service.

## Summary of the Invention

The present invention advances the flexibility and configurability of converged computer systems. It provides a method for managing multiple channel maps from different input devices within a single system. The invention provides a modular facility which provides a device database of characteristics and system connections for each media source or device. It accepts a set of channel designations from each device and automatically translates or remaps them into a set of logical channels unique within the system. Another aspect of the invention integrates on-line programming guides or listings for multiple

10	Brief Description of the Drawing
----	----------------------------------

Fig. 3 is a block diagram of portions of the system of Figs. 1 and 2 that participate in the present invention.

Fig. 7, comprising Figs. 7A and 7B, is a flowchart of a method for constructing the channel-map database of Fig. 6.

The following detailed description refers to the accompanying drawing which forms a part hereof, and which shows by way of illustration specific preferred embodiments in which the invention may be practiced. These embodiments are described in sufficient detail to enable those skilled in the art to practice the invention. Other embodiments may be employed, and logical, mechanical and electrical changes may be made without departing from the spirit and scope of the present invention. The following detailed description is, therefore, not to be taken in a limiting sense; rather, the scope of the invention is defined only by the appended claims.

Fig. 1 shows the hardware of a convergence system 100 that serves as an environment for the present invention. A number of signal-capture devices 110 intercept media signals from a number of sources. For example, a VHF/UHF antenna may receive off-the-air RF television signals, a satellite dish may receive direct-broadcast satellite (DBS) services in the gigahertz range, a cable connection box may receive commercial wired cable transmissions, and a modem may receive digitized images and sounds. Other conventional signal sources may be accommodated as well. Standard signal receivers 120 convert the raw media signals into forms suitable for storage, for presentation to a user, or for other purposes. For example, a television tuner may convert the RF signal from an antenna to baseband audio and video (A/V) signals for real-time display. The channel map for off-the-air TV channels are numbers from '2' to '69'. A video cassette recorder (VCR) may store A/V signals derived from an antenna for later playback. VCRs have no channels, unless they are connected to a signal source such as an antenna. A DBS modem may demodulate satellite signals from a dish antenna; many such modems can also process RF TV signals. Satellite services commonly employ a map or set having channel numbers above '100'. A VCR may also receive and store cable-TV signals from a connection box. Again, many other types of known and future signal receivers 120 may be coupled to system 100; some of them may be physically located within a personal computer system 150. Conventional control functions for these devices may be achieved by wired interfaces such as those described in the IEEE-1394 standard, or by wireless means such as infrared or RF.

An audio/video multiplexer 130 couples to receivers 120 and selects one of their output media signals; it may be physically located in computer system 150, in a television receiver, in a set-top box, or in any other convenient place. The selected output media signal is presented to a user on an output subsystem 140 such as output device 141, which is, for example, a large, high-quality video monitor capable of displaying standard TV signals, satellite or HDTV (high-definition television), and character/image data from a computer system 150. Sound system 142 preferably includes a multichannel amplifier and a set of loudspeakers of the "home theater" type. Although multiplexer 130 normally selects one source for presentation on the output devices, it may also be capable

of selecting and mixing signals from multiple signal receivers 120, including signals from computer system 150.

A programmable digital processing system 150 may, for example, include the components and functions of a conventional personal computer (PC).

5 In a convergence system, however, the main unit 151 may be physically located at a greater distance from output devices 140 than is the case for a desktop or business PC, and coupled thereto by a wired or wireless connection 152 through multiplexer 130. That is, a convergence system treats PC 150 as only one of a number of more or less equal signal sources for presentation devices 140. Main  
10 unit 151 may transmit control commands, as well as A/V data, to multiplexer 130. Also, a convergence system usually couples input devices such as keyboard 153 and pointing device 154 to the main unit through a wireless interface, either RF or infrared, rather than by wires. Pointing device 154 usually takes the form similar to that of a TV remote, and includes a trackball or other means that can  
15 be operated independently of a work surface. In some cases, device 154 might control multiplexer 130 directly, and could even perform some of the functions described in connection with system 151. Computer 150 further includes a standard network interface 155 such as a data modem for connection to providers of on-line services, local-area networks, and the like.

20 Fig. 2 is an overview of a preferably software architecture 200 for providing convergence functions in system 100, Fig. 1. Commonly assigned application entitled "Architecture for Convergence Systems," filed on even date herewith and hereby incorporated by reference herein, describes this architecture in greater detail.

25 For the present purpose, it is sufficient to note that driver layer 210 contains a number of modular drivers of conventional construction for controlling the system hardware 100, and for interfacing to functions of a conventional operating system such as Microsoft® Windows95®. Drivers represent the lowest level of abstraction of a software architecture, and include  
30 application programming interfaces (APIs). A services layer 220 of modular system services provides a higher level of abstraction. System services interface with drivers to provide frequently used functions such as scheduling events for receivers 120, entering and enforcing parental-control restrictions, and storing

"favorite place" information for users. The present invention creates services at this level. User-interface layer 230 provides a number of modules allowing a user to interact with components in both services layer 220 and driver level 210. For example, an interface could provide facilities for a user to enter or update specific items in a parental controls service. "View" interfaces generally comprise full-screen interfaces covering multiple related functions, such as a TV View for programming and controlling media receivers 120, and a PC View providing a desktop for executing application programs 202 from processing system 150. "Overlays" are mostly not independent interfaces; rather, they cooperate with and extend view interfaces. Overlays primarily provide contextual information and means for navigating a hardware facility.

Fig. 3 is a block diagram of portions of the system of Figs. 1 and 2 that participate in the channel-mapping function of software 200 for system 100.

TV-services module 310, one of the services in layer 220, controls multiplexer 130 to select among input devices 120 for presentation on output devices 140, and controls the selected device to tune to a particular channel on that device. Device selection and channel tuning may occur in response to a contemporaneous user selection of a specific event on a particular channel of a particular device via a TV-view interface 320 in architecture layer 230. The interface employs EPG ("electronic program guide") content-services module 330 to present choices of events. (Other sources, such as an application program 202 running on PC 150, may also interface with TV-services module 310 for this purpose.)

EPG module 330 provides a function for recording and organizing programs or other events available from media devices 120. Although the internal operation of module 330 is not relevant here, an understanding of its overall functions is helpful. Some media sources provide in-band guides for their programming. For example, DBS modem 112 continually receives signals representing broadcast information as to what events will occur on particular tunable satellite channels at specific times. Other companies—some of which themselves provide media and some of which do not—furnish out-of-band program guides in electronic form. For example, a user may subscribe to electronic program listings transmitted periodically over the Internet and

received into system 100 via network interface 155, which may be a modem or similar device. EPG module 330 integrates and stores electronic program guides into a database 340. Fig. 4 illustrates a structure 400 for storing this information. A set 410 of records have columns 420 for storing information including a  
5 unique event identifier 421, a title 422, a designation 423 of the source providing the event, the physical channel 424 within source 423, and a start time and date for the event; other information may be kept in database 340 as well. In Fig. 4, records 411-413 show a single TV show available from three different sources at two different times. Record 411 indicates that the show is broadcast on a  
10 channel that DBS service 123 identifies as '156'. The program starts at 7pm on September 17. Record 412 specifies a broadcast of this show on VHF TV channel '4' an hour later. Record 413 logs the show at the same time on a local cable service. The cable channel designation, '156' is—strictly coincidentally—the same as that for the DBS broadcast in record 411.

15 Module 310 stores information about media input devices connected to system 100 in a device database 350. Fig. 5 describes a structure 500 for this database. A set 510 of records includes columns 520 for storing certain characteristics of each device. Column 521 holds a device name by which the system knows each connected receiver 120. Column 522 specifies the input 522  
20 to which that device is coupled. Column 523 contains a flag indicating whether or not the device is tunable, i.e., has multiple channels. Column 524 includes an identifier naming the source 110 of its signals. For example, record 511 asserts that RF tuner 121 feeds input V1 of multiplexer 130 in Fig. 1, that it is tunable to different channels, and that RF antenna 111 sources its signals. A single receiver  
25 device may possess more than one record; records 513 and 514 both name DBS modem 123, but indicate that, like most satellite receivers, it can be connected to a local-channel source 111 as well as to its own dish 112. The structure 500 of database 350 permits multiple sources, allows any combination of tunability, and admits more than one input connection for any device. Other information may  
30 be recorded if desired. The database structure may comprise a simple table or a more complex entity.

Channel-mapping services module 360 builds, maintains, and reads a channel-map database 370 for module 310. Fig. 6 shows a structure 600 for

database 370. A set 610 of individual records 611-614 includes columns for designating independent logical and physical designations 621 and 622 for the same channel, for specifying a signal source 623 for that channel, and for naming a primary device 624 for receiving the channel into multiplexer 130, Fig. 1.

5 Logical channel numbers—or other designations—621 are unique within system 100, and have no necessary relation to physical channels, transmission channels, or any other designation employed by their source. They create a linear name space across the entire system. The user, however, never need be aware of channel 621; interface 320 preferably displays only the physical channel

10 designation 622 to the user. Module 320, of course, must use the physical channel number 622 for tuning a selected device. (Satellite receivers commonly convert their physical channel numbers internally to another set of transmission channels.) Column 623 designates a source 110 for the logical channel. Column 624 names one of the receiver devices 120 as the primary device for receiving

15 the logical channel, the one that is normally preferred by the user. Column 625 names one or more secondary source for the same signal. For example, the RF tuner primary device in record 613 could be unavailable for some reason; column 625 specifies that the signal from physical channel '4' of the RF tuner is also obtainable on logical channel '01' -- that is, on physical channel '156' of the

20 satellite dish. A comparison of records 611 and 614 demonstrates that two channels having the same physical designation, '156', have different logical designations, '01' and '04'. Database structure 600 may also include a name for presentation to the user, in column 626. Thus, for example, the name "Fox" can be displayed for any of the logical channels in records 611, 612, and 614, which

25 all represent a Fox® network station. The entries in column 626 have no fixed significance; they may represent a source name from a program guide, an arbitrary designation entered by the user, or any other information. Database 370 may include additional columns containing further information concerning each logical channel. The form of database 370 may vary from a simple table or

30 list in memory to a complex application; its implementation is not material to the invention.

Fig. 7 describes the operation 700 of the invention within the architecture 300, Fig. 3.

When the connection of an input device 120 to a signal source 110 or to multiplexer 130 changes, a user employs a user interface 320 to call TV-services module 310, at 710 in Fig. 7. If a device is disconnected from a source or from a multiplexer input, step 711 causes step 712 to access the device database 350.

- 5 Step 713 receives an identification of the particular connection that has been broken. Step 714 deletes the record specifying that connection, and passes control to exit the service. When a new connection is made, step 711 executes step 715, which requests the user to identify the device 120, its port number in multiplexer 130, and its source 110. Step 716 may then read a number of
- 10 characteristics from the device itself, such as whether it is capable of tuning multiple channels. Step 717 then builds a new record containing the information in columns 520, Fig. 5. Step 718 adds the record to device database 350, and passes control to exit 702.

- The arrival of a new event listing from an in-band or out-of-band on-line
- 15 provider initiates a call to EPG services module 330 at 720 in Fig. 7. Step 721 detects the listing, and step 722 reformats its entries if necessary. For each event record in the listing, step 723 causes step 724 to translate the physical channel in the listing to the equivalent logical channel. Because the combination of device and physical channel is unique, this translation may be accomplished by
- 20 accessing map database 370 using columns 622 and 624 as a composite key, then extracting the value of column 621. If step 725 determines that the current device/physical-channel combination is already present in database 370, then step 726 builds a new event record from the listing information and the logical channel designation, step 727 stores the record, and control returns to step 723 to
- 25 process the next record in the listing.

- If step 725 detects a device/physical-channel key that is not present in database 370, it calls channel-map services module 360, at 730 in Fig. 7. Step 731 first asks whether the device is valid: that is, whether the device name is present in the set of connected receivers 120, and, if so, whether the listing
- 30 channel can be tuned by that device. If the list channel is invalid, step 732 signals an error and returns to step 723. For a valid new channel, step 733 assigns a new logical channel number, one which is distinct from all the channel numbers in column 621. Step 734 then accesses device database 350 in order to

obtain the remaining information required for a map-database record. Step 735 builds the new record, and step 736 adds it to the channel map database 370. Control then returns to EPG services module at step 726, to build an E.G. record for the current event on the new channel.

- 5           Although specific embodiments have been illustrated and described herein, those of ordinary skill in the art will appreciate that any elements or arrangements of elements capable of achieving the same purpose may be substituted for the specific forms shown. This patent is intended to cover all adaptations or variations of the invention, limited only by the following claims
- 10   and equivalents thereof.

**I Claim:**

1. A method, performed in an electronic data-processing system, for managing a plurality of channel maps, each channel map associated with a different media  
5 source, and each channel map including a plurality of channels, each channel having a physical channel designation, the method comprising:  
    receiving a plurality of physical channel designations from at least two media sources;  
    translating said received physical channel designations to a plurality of  
10 logical channel designations, each logical channel designation being distinct from any other logical channel designation;  
    constructing a record for each of said logical channel designations, said record including the matching physical channel designation which was translated to said logical channel designation and including an identification of the media  
15 source from which the translated physical channel designation was received; and  
    assembling a channel-map database comprising a plurality of said records.
2. A method according to claim 1, wherein said receiving step comprises:  
20      receiving a guide, the guide listing multiple events, each event associated with one of said physical channel designations and one of said media sources;  
    and  
    extracting said physical channel designations and said media sources for each event listing in said guide.
- 25 3. A method according to claim 2, wherein said guide is an in-band guide received directly from one of said media sources.
4. A method according to claim 2, wherein said guide is an out-of-band on-line  
30 guide received electronically from a source other than one of said media sources.

5. A method according to claim 1, wherein said translating step comprises:  
comparing a first of said physical channel designations to said channel-map database;  
determining whether said physical channel designation is present in said  
5 channel-map database;  
if said physical channel designation is present in said channel-map database, repeating said comparing and determining steps for the next physical channel designation, until all physical channel designations have been processed;  
and  
10 if said physical channel designation is not present in said channel-map database, carrying out said translating, constructing, and assembling steps for said physical channel designation.
6. A method according to claim 5, wherein different media sources have channel  
15 maps containing different sets of physical channel designations.
7. A method according to claim 1, wherein said constructing step comprises:  
obtaining a predetermined characteristic of each said media source; and  
including said predetermined characteristic in said record.  
20
8. A method according to claim 7, wherein multiple characteristics of each said  
media source are obtained and included in said record.
9. A method according to claim 7, wherein said characteristic is obtained from a  
25 device database within said electronic data-processing system.
10. A method according to claim 1, wherein said assembling step comprises  
adding new records sequentially to said channel-map database.
- 30 11. A method according to claim 1, further comprising:  
constructing a device database comprising a set of characteristics for each  
of said media sources, one of said characteristics being said identification of said  
media source; and

including at least one of said characteristics in addition to said identification in each said record.

12. A method according to claim 11, wherein constructing said device database  
5 comprises:

receiving source information for each of said media sources, said source information including said identification of said media source, connection data specifying the connection of said media source to said system, and at least one further characteristic for said media source; and

10 including at least some of said source information in addition to said identification in each said record.

13. A data structure for a data processing system for managing a plurality of channel maps, each channel map associated with a different media source, and  
15 each channel map including a plurality of channels, each channel having a physical channel designation, the data structure comprising:

a plurality of rows, each row including a logical channel designation, each logical channel designation being distinct from any other logical channel designation, a physical channel designation related to said logical channel  
20 designation, and an identification of the media source for said physical channel designation;

a first column containing said logical channel designation;

a second column containing said physical channel designation; and

a third column containing said media source identification.

25

14. A data structure according to claim 13, further including a fourth column containing a primary media input device associated with said media source.

15. A data structure according to claim 14, further including a fifth column  
30 containing a secondary logical channel designation associated with said logical channel designation in said first column.

16. A data structure according to claim 15, further comprising a sixth column containing human-readable information for said logical channel designation.
17. A method for managing multiple information channels from multiple input devices in a multimedia system, comprising:
- 5 reading a plurality of physical channel designations associated with a plurality of physical channels received from each of said input devices;
- mapping each of said physical channel designations to a logical channel designation; each logical channel designation differing from all other logical
- 10 channel designations; and
- retrieving one of said physical channels using said logical channel designation.
18. A method according to claim 17, wherein each of said input devices is
- 15 coupled to a source of media input signals.
19. A method according to claim 17, further comprising:
- recording a record for each of said logical channel designations, said record including the physical channel designation mapped to said logical channel
- 20 designation and including an identification of the input device from which said physical channel designation was received.
20. A method according to claim 19, further comprising assembling a table including all of said records.

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 0 601 553 A (GRUNDIG EMV) 15 June 1994	1,7-14, 17-20
Y	see abstract see column 1, line 54 - column 5, line 33 see figure 1 see claim 1	2-4
X	EP 0 453 937 A (SAMSUNG ELECTRONICS CO LTD) 30 October 1991 see abstract see column 3, line 53 - column 4, line 11 see figure 3	1,7-12
X	US 5 257 106 A (MARUOKA KAZUHISA) 26 October 1993 see abstract see column 4, line 13 - column 4, line 30 see figure 2	1,7,17, 18
	--- -/--	

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

\* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

13 April 1999

Date of mailing of the international search report

21/04/1999

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,  
Fax: (+31-70) 340-3016

Authorized officer

Hampson, F
